1 Lie Groups

1.1 Beginning Details

A Lie group is a group $G$ with the structure of a smooth manifold, such that the two maps

$$G \to G, x \mapsto x^{-1} \quad \text{and} \quad G \times G \to G, (x, y) \mapsto xy$$

are smooth. This last condition is equivalent to requiring that the single map $G \times G \to G, (x, y) \mapsto xy^{-1}$ be smooth.
A Lie group $G$ comes with a lot of structure. There is a distinguished element $e \in G$, the group identity. This means there is a distinguished tangent space, $T_e G \subset TG$. For each $g \in G$, we obtain three maps:

1. left multiplication: $L_g: G \rightarrow G, \; h \mapsto gh$;
2. right multiplication: $R_g: G \rightarrow G, \; h \mapsto hg$; and
3. conjugation: $\Psi_g: G \rightarrow G, \; h \mapsto L_g \circ R_g^{-1}(h) = R_{g^{-1}} \circ L_g(h) = ghg^{-1}$.

Each of these maps is smooth, and in fact they are all diffeomorphisms. The inverses of $L_g$, $R_g$, and $\Psi_g$ are $L_g^{-1}$, $R_g^{-1}$, and $\Psi_g^{-1}$, respectively. They are also group homomorphisms, so they are **Lie group isomorphisms**. Also, note that the left and right multiplication maps commute with each other. For all $g, h \in G$, we have $L_g \circ R_h = R_h \circ L_h$.

**Remark 1.1.** For whatever reason, most of Lie theory is centered around the left multiplication maps, but it could just as well have been developed using the right multiplication maps.

The three maps above are **canonical** with respect to the Lie group structure. Therefore all tangent spaces of $G$ are canonically isomorphic. For $g, h \in G$, we have the canonical linear isomorphisms

$$T_g(L_{hg^{-1}}): T_g G \rightarrow T_h G \quad \text{and} \quad T_g(L_{gh^{-1}}): T_h G \rightarrow T_g G.$$ 

Thus all tangent spaces of $G$ are canonically isomorphic to the distinguished tangent space of $G$, $T_e G$.

Let $g \in G$. Because $\Psi_g(e) = geg^{-1} = e$, we have a canonical operator on the distinguished tangent space $T_e G$, given by $T_e \Psi_g: T_e G \rightarrow T_e G$. We denote this map by $\text{Ad}(g)$. Since $\Psi_g$ is a diffeomorphism, $\text{Ad}(g) = T_e \Psi_g$ is a linear isomorphism, so $\text{Ad}(g) \in \mathfrak{so}(T_e G)$, so

$$\text{Ad}: G \rightarrow \mathfrak{so}(T_e G)$$

is a group representation of $G$, called the **adjoint representation**.

Recall that $\mathfrak{so}(T_e G)$ is the inverse image of the open set $\mathbb{R} \setminus \{0\}$ under the continuous (and smooth) map $\text{det}: \mathfrak{gl}(T_e G) \rightarrow \mathbb{R}$, so it is an open subset of the vector space $\mathfrak{gl}T_e G$. 

Thus $\mathfrak{GL}(T_e G)$ is a smooth manifold with tangent bundle $\mathfrak{GL}(T_e G) \times \mathfrak{gl}(T_e G)$. Therefore the tangent map of $\text{Ad}$ at the identity $e$ is a map $T_e \text{Ad} : T_e G \to \mathfrak{gl}(T_e G)$. By slightly restructuring the domain and codomain, we obtain a map

$$\text{ad} : T_e G \times T_e G \to T_e G, \quad (v, w) \mapsto \text{ad}(v)w := (T_e \text{Ad})(v)w.$$ 

Note that $\text{ad}$ is linear in both $v$ and $w$, so $\text{ad}$ is bilinear.

### 1.2 The Exponential Map and Useful Curves

For each Lie group $G$, we have the **exponential map**, $\exp_G : T_e G \to G$. We usually omit the subscript from $\exp$ if there is no confusion. It is defined by means of **one-parameter subgroups**, which we will not discuss here. The exponential map is characterized by the fact that if $v \in T_e G$ and $s, t \in \mathbb{R}$, then

$$\exp \left( (s + t)v \right) = \exp(sv) \cdot \exp(tv) = \exp(tv) \cdot \exp(sv),$$

and the following Lemma.

**Lemma 1.2.** Let $v \in T_e G$, and let $c : \mathbb{R} \to G$ be the smooth curve given by $t \mapsto \exp(tv)$. Then $\dot{c}(0) = v$.

Note that $\mathfrak{GL}(T_e G)$ is a Lie group under multiplication, and that its tangent space at the identity is essentially $\mathfrak{gl}(T_e G)$. Therefore we have a map

$$\exp_{\mathfrak{GL}(T_e G)} : \mathfrak{gl}(T_e G) \to \mathfrak{GL}(T_e G).$$

Since $\text{ad}(v) \in \mathfrak{gl}(T_e G)$ for all $v \in T_e G$, we have

$$\exp_{\mathfrak{GL}(T_e G)}(\text{ad}(v)) \in \mathfrak{GL}(T_e G).$$

It is natural to ask what element of $\mathfrak{GL}(T_e G)$ this might be.

**Theorem 1.3.** Let $v \in T_e G$. Then

$$\text{Ad}(\exp_G v) = \exp_{\mathfrak{GL}(T_e G)}(\text{ad}v)$$

3
Remark 1.4. Dropping the subscripts from the exponential maps, we obtain the commutative diagram
\[ \begin{array}{ccc}
\mathfrak{g} & \xrightarrow{\text{ad}} & \mathfrak{gl}(T_eG) \\
\exp & \downarrow & \exp \\
G & \xrightarrow{\text{Ad}} & \mathcal{L}(T_eG)
\end{array} \]

Combining Theorem 1.3 and Lemma 1.2 yields the following result.

Proposition 1.5. Let \( v, w \in T_eG \), and let \( c: \mathbb{R} \to T_eG \) be the smooth curve given by \( t \mapsto \text{Ad}(\exp(tv))(w) \). Then
\[ \dot{c}(0) = ([X, Y]). \]

2 The Lie Algebra of a Lie Group

2.1 General Lie Algebras

A \textbf{Lie algebra} is a real vector space \( L \) equipped with a skew-symmetric bilinear map \( L \times L \to L, (v, w) \mapsto [v, w] \), called a \textbf{bracket}, which satisfies the \textbf{Jacobi identity}
\[ [u, [v, w]] + [v, [w, u]] + [w, [u, v]] = 0 \]
for all \( u, v, w \in L \). Two standard examples are the set of vector fields on a manifold with the Lie bracket, or the set of \( n \times n \) real (or complex) matrices with the bracket
\[ [A, B] := AB - BA. \]

2.2 The Tangent Space at the Identity

The tangent space \( T_eG \) at the identity is a real vector space. Using the three classes of maps inherent in the Lie group structure, we can equip \( T_eG \) with a bracket that makes it a Lie algebra. The vector space \( T_eG \) with this bracket is denoted \( \mathfrak{g} \), and called the \textbf{Lie algebra of the Lie group} \( G \).

Each step in the construction of the Lie bracket for \( \mathfrak{g} \) is \textit{natural}, in the sense that it is preserved by smooth homomorphisms between Lie groups. Let \( H \) be another Lie group...
and \( \rho: G \to H \) be a smooth homomorphism. The naturality of each step below will be shown by a commutative diagram involving \( G, H, \) and \( \rho. \)

\[
\begin{array}{ccc}
G & \overset{\rho}{\longrightarrow} & H \\
\Psi_g & \downarrow & \Psi_{\rho(g)} \\
G & \overset{\rho}{\longrightarrow} & H
\end{array}
\]

As described above, for each \( g \in G \), we obtain a Lie group isomorphism \( \Psi_g: G \to G \) and a linear isomorphism \( \text{Ad}(g): T_eG \to T_eG \). Then \( \text{Ad}(g) \in \mathfrak{gl}(T_eG) \), so we have a smooth homomorphism \( \text{Ad}: G \to \mathfrak{gl}(T_eG). \)

\[
\begin{array}{ccc}
T_eG & \overset{\text{Ad}(g)}{\longrightarrow} & T_eH \\
\downarrow & & \downarrow \text{Ad}(\rho(g)) \\
T_eG & \overset{\text{Ad}(\rho(g))}{\longrightarrow} & T_eH
\end{array}
\]

We define a bracket on \( T_eG \) by \([v, w] = \text{ad}(v)w\). It remains to be shown that this bracket is anti-symmetric and satisfies the Jacobi identity. We will not prove this here, although it will follow from the fact that the Lie bracket of vector fields satisfies these properties.

\[
\begin{array}{ccc}
T_eG & \overset{T_e\rho}{\longrightarrow} & T_eH \\
\downarrow \text{ad}(v) & & \downarrow \text{ad}(T_e\rho)v \\
T_eG & \overset{T_e\rho}{\longrightarrow} & T_eH
\end{array}
\]

### 2.3 Left Invariant Vector Fields

**Definition 2.1.** Let \( f: \mathcal{M} \to \text{ndld} \) be a diffeomorphism between smooth manifolds, and let \( X \in \mathfrak{x}(\mathcal{M}) \) and \( Y \in \mathfrak{x}(\mathcal{N}). \) The pushforward of \( X \) by \( f \) is

\[
f_*(X) := Tf \circ X \circ f^{-1} \in \mathfrak{x}(\mathcal{N}),
\]

and the pullback of \( Y \) by \( f \) is

\[
f^*(Y) := Tf^{-1} \circ Y \circ f \in \mathfrak{x}(\mathcal{M}).
\]
Note that 
\[ f^*(Y) = (f^{-1})_*(Y) \quad \text{and} \quad f_*(X) = (f^{-1})^*(X). \]

**Definition 2.2.** A vector field \( X \in \mathfrak{X}(G) \) is called **left invariant** if
\[ (T_hL_g)(X(h)) = X(L_g(h)) = X(gh) \]
for all \( g, h \in G \). This means the following diagram commutes for each \( g \in G \).

\[
\begin{array}{c}
G \xrightarrow{X} TG \\
L_g \downarrow \quad T_eL_g \\
G \xrightarrow{X} TG
\end{array}
\]

The set of all left invariant vector fields on \( G \) is denoted \( \mathcal{L}(G) \).

**Remark 2.3.** Let \( X \in \mathcal{L}(G) \). Then \( TL_g \circ X = X \circ L_g \) for all \( g \in G \). Thus
\[ TL_g \circ X \circ (L_g)^{-1} = X \quad \text{and} \quad (TL_g)^{-1} \circ X \circ L_g = X \]
for all \( g \in G \). Certainly if a vector field satisfies either of the above equations for all \( g \in G \) it must be left invariant. Therefore \( \mathcal{L}(G) \) is the set of vector fields invariant under pushforward by left multiplication, which is also the set of vector fields invariant under pullback by left vector fields.

The set \( \mathcal{L}(G) \) is clearly a real vector space, but it is not clear what its dimension is. There’s no reason to assume that the dimension be finite, but it is. It’s actually quite a surprise.

Recall the Lie bracket of vector fields. This can be defined in terms of flows of vector fields, or in terms of derivations. Let \( X, Y \in \mathfrak{X}(G) \) be vector fields, let \( \Phi^t_X, \Phi^t_Y \) denote their respective flows, and let \( \mathcal{D}_X, \mathcal{D}_Y \) denote their respective associated derivations. Then the **Lie bracket** \([X, Y] \in \mathfrak{X}(G)\) is the unique vector field such that
\[
[X, Y] = \mathcal{L}_XY := \frac{d}{dt} \big|_{t=0}(\Phi^t_X)^*Y,
\]
or equivalently,
\[
\mathcal{D}[X,Y] = \mathcal{D}_X \circ \mathcal{D}_Y - \mathcal{D}_Y \circ \mathcal{D}_X.
\]
The pushforward of vector fields by diffeomorphisms preserves the Lie bracket [see page 144 in Conlon’s *Differentiable Manifolds, 2nd Edition*]. Since left invariant vector fields can be categorized as those that are invariant under pushforward by all left multiplications, this implies that the Lie bracket of two left invariant vector fields is also left invariant. Therefore $\mathcal{L}(G)$ equipped with the Lie bracket is a Lie algebra.

2.4 $T_eG \cong \mathcal{L}(G)$ as Vector Spaces

We have two Lie algebras associated with $G$: the tangent space at the identity, $T_eG$, with the bracket induced by $\text{ad}$, and the left invariant vector fields, $\mathcal{L}(G)$, with the Lie bracket. In this section we will demonstrate that they are isomorphic as vector spaces.

Define a map $\nu: T_eG \to X(G)$ by

$$\nu_\xi(g) = T_eL_g(\xi)$$

for all $\xi \in T_eG$ and $g \in G$. Because tangent maps are linear, so is $\nu$. For all $\xi, \eta \in T_eG$ and $g, h \in G$ we have

$$(T_hL_g)(\nu_\xi(h)) = (T_hL_g)(T_eL_h(\xi)) = T_e(L_g \circ L_h)(\xi) = T_eL_{gh}(\xi) = \nu_\xi(gh) = (\nu_\xi \circ L_g)(h).$$

Therefore $\nu_\xi$ is left invariant, so $\nu$ really is a map $T_eG \to \mathcal{L}(G)$. Its inverse is (immediately) given by the map

$$\mathcal{L}(G) \to T_eG, \quad X \mapsto X(e) \in T_eG.$$

2.5 $T_eG \cong \mathcal{L}(G)$ as Lie Algebras

To show that $T_eG$ and $\mathcal{L}(G)$ are isomorphic as Lie algebras as well as vector fields, we must show that the map

$$\nu: T_eG \to \mathcal{L}(G)$$

preserves the brackets, i.e.

$$\nu_{\text{ad}(\xi)\eta} = [\nu_\xi, \nu_\eta]$$

for all $\xi, \eta \in T_eG$. Since the Lie bracket of vector fields can be described easily in terms of flows, it might be helpful to know what the flows of these vector fields look like.
Claim 2.4. Let $\xi \in T_eG$ and $g \in G$. Then the flow of $\nu_\xi$ through $g$ is the curve $c : \mathbb{R} \to G$ given by

$$c(t) = L_g \circ \exp(t \xi).$$

Proof. Note that $c(0) = L_g \circ \exp(\vec{0}) = L_g(e) = g$. Let $t \in \mathbb{R}$. Then

$$c(t) = \frac{d}{ds} \bigg|_{s=t} c(t) = \frac{d}{ds} \bigg|_{s=0} c(s + t)$$

$$= \frac{d}{ds} \bigg|_{s=0} L_g \circ \exp((s + t)\xi) = \frac{d}{ds} \bigg|_{s=0} L_g \circ \exp((t + s)\xi)$$

$$= \frac{d}{ds} \bigg|_{s=0} L_g \exp(t\xi) \cdot \exp(s\xi) = \frac{d}{ds} \bigg|_{s=0} L_g \circ L_{\exp(t\xi)} \left( \exp(s\xi) \right)$$

$$= \frac{d}{ds} \bigg|_{s=0} L_{g \exp(t\xi)} \left( \exp(s\xi) \right)$$

$$= (T_eL_g \exp(t\xi)) \left( \frac{d}{ds} \bigg|_{s=0} \exp(s\xi) \right)$$

$$= (T_eL_g \exp(t\xi))(\xi)$$

$$= \nu_\xi(g \exp(t\xi))$$

$$= \nu_\xi(c(t)).$$

QED

Theorem 2.5. Let $\xi, \eta \in T_eG$. Then

$$\nu_{\text{ad}(\xi)\eta} = [\nu_\xi, \nu_\eta].$$

Proof. Recall that the flow of $\nu_\xi$ at time $t \in \mathbb{R}$ is the map $G \to G$ given by $R_{\exp(t\xi)}$. Let $g \in G$. Then using the definition of $\Psi$, $\text{Ad}$, and $\nu$, the linearity of tangent maps, and Proposition ??, we calculate

$$[\nu_\xi, \nu_\eta](g) = \frac{d}{dt} \bigg|_{t=0} \left( (R_{\exp(t\xi)})_{\text{eta}} \right)(g)$$

$$= \frac{d}{dt} \bigg|_{t=0} TR_{\exp(t\xi)} \circ \nu_{\text{eta}} \circ R_{\exp(t\xi)}^{-1}(g)$$

$$= \frac{d}{dt} \bigg|_{t=0} TR_{\exp(t\xi)} \circ \nu_{\text{eta}}(g \exp(-t\xi))$$

$$= \frac{d}{dt} \bigg|_{t=0} TL_g \exp(-t\xi)(\eta)$$
\[
\begin{align*}
\frac{d}{dt}\bigg|_{t=0} T\left(R_{\exp(t\xi)} \circ L_{g \exp(-t\xi)}\right)(\eta) \\
= \frac{d}{dt}\bigg|_{t=0} T\left(R_{\exp(t\xi)} \circ L_g \circ L_{\exp(-t\xi)}\right)(\eta) \\
= \frac{d}{dt}\bigg|_{t=0} T\left(L_g \circ R_{\exp(t\xi)} \circ L_{\exp(t\xi)}^{-1}\right)(\eta) \\
= \frac{d}{dt}\bigg|_{t=0} (TL_g) \circ (T \Psi_{\exp(t\xi)})(\eta) \\
= \frac{d}{dt}\bigg|_{t=0} (TL_g) \circ \text{Ad}(\exp t\xi)(\eta) \\
= (TL_g) \left(\frac{d}{dt}\bigg|_{t=0} \text{Ad}(\exp t\xi)\right)\eta \\
= (TL_g)[\xi, \eta] \\
= \nu_{[\xi, \eta]}(g). \\
\end{align*}
\]
