March 1999

Abstract

We develop the exact constant of the risk asymptotics in the uniform norm for density estimation. This constant has first been found for nonparametric regression and for signal estimation in Gaussian white noise. Hölder classes for arbitrary smoothness index $\beta > 0$ on the unit interval are considered. The constant involves the value of an optimal recovery problem as in the white noise case, but in addition it depends on the maximum of densities in the function class.

\textit{Keywords:} Density estimation, exact constant, optimal recovery, uniform norm risk, white noise

RUNNING TITLE: Asymptotic minimax density estimation

\textsuperscript{*} To whom correspondence should be addressed.
1 Introduction and Main Result

Recently in Korostelev (1993) an asymptotically minimax exact constant has been found for loss in the uniform norm, for Gaussian nonparametric regression when the parameter set is a Hölder function class. This risk bound represents an analog of the now classical $L_2$-minimax constant of Pinsker (1980) valid for a Sobolev function class. Donoho (1994) extended Korostelev’s (1993) result to signal estimation in Gaussian white noise and showed it to be related to nonstochastic optimal recovery.

Here we consider density estimation from i. i. d. data with a sup-norm loss. Consider a sample $X_1, \ldots, X_n$ of i. i. d. observations having a probability density $f = f(x)$ in the interval $0 \leq x \leq 1$. Let $\beta, L$ be some positive constants, and let $\Sigma(\beta, L)$ be the class of densities

$$\Sigma(\beta, L) = \{g : \int_0^1 g = 1, \ g \geq 0, \ \text{and} \ |g^{[\beta]}(x_1) - g^{[\beta]}(x_2)| \leq L|x_1 - x_2|^{\beta - \lfloor \beta \rfloor}, \ 0 \leq x_1, x_2 \leq 1\}$$

where $\lfloor \beta \rfloor$ is the greatest integer strictly less than $\beta$. Assume that the density $f$ belongs a priori to $\Sigma(\beta, L)$. Consider an arbitrary estimator $\hat{f}_n = \hat{f}_n(x)$ measurable w.r.t. the observations $X_1, \ldots, X_n$. We define the discrepancy of $\hat{f}_n(x)$ and the true density $f(x)$ by the sup–norm $||\hat{f}_n - f||_\infty$ where

$$||f||_\infty = \sup_{0 \leq x \leq 1} |f(x)|.$$

Denote by $P_f^{(n)}$ the probability distribution of the observations $X_1, \ldots, X_n$, and by $E_f^{(n)}$ the expectation w.r.t. $P_f^{(n)}$. Let $w(u), \ u \geq 0$, be a continuous increasing function which admits a polynomial majorant $w(u) \leq W_0(1 + u^\gamma)$ with some positive constants $W_0, \gamma$, and such that $w(0) = 0$. Introduce the minimax risk

$$r_n = r_n(w(\cdot); \beta, L, b) = \inf_{\hat{f}_n} \sup_{f \in \Sigma(\beta, L, b)} E_f^{(n)} w(\psi_n^{-1}||\hat{f}_n - f||_\infty)$$

(1)
where \( \psi_n = ((\log n)/n)^{\beta/(2\beta+1)} \) is the optimal rate of convergence (cf. Khasminskii (1978), Stone (1982), Ibragimov and Khasminskii (1982)). The main goal of this paper is to find the exact asymptotics of the risk (1). To do this we need two additional definitions. First, note that the densities in \( \Sigma(\beta,L) \) are uniformly bounded, i. e.

\[
B^* = B^*(\beta,L) = \max_{f \in \Sigma(\beta,L)} \max_{0 \leq x \leq 1} f(x) < +\infty. \tag{2}
\]

An argument for this based on imbedding theorems, as well as further information on the value of \( B^* \) is given in an appendix (section 4). Secondly, denote by \( \Sigma_0(\beta,L) \) an auxiliary class of functions on the whole real line:

\[
\Sigma_0(\beta,L) = \{ f : \| f^{[\beta]}(x_1) - f^{[\beta]}(x_2) \| \leq L|x_1 - x_2|^{\beta-\lfloor \beta \rfloor}, \ x_1, x_2 \in \mathbb{R}^1 \}.
\]

Let \( \| g \|_2 \) denote the \( L_2 \)-norm of \( g \). Define the constant

\[
A_\beta = \max \left\{ g(0) \mid \| g \|_2 \leq 1, \ g \in \Sigma_0(\beta,1) \right\}. \tag{3}
\]

**Theorem.** For any \( \beta > 0, L > 0 \) and for any loss function \( w(u) \) the minimax risk (1) satisfies:

\[
\lim_{n \to \infty} r_n = w(C)
\]

where

\[
C = C(\beta, L, B_*) = A_\beta \left( \frac{2B_*L^{1/\beta}}{2\beta+1} \right)^{\beta/(2\beta+1)},
\]

and the constants \( B_* = B^*(\beta,L) \) and \( A_\beta \) are defined by (2) and (3) respectively.

The proof of the corresponding upper and lower asymptotic risk bounds is developed in sections 2 and 3. A more concise argument based on asymptotic equivalence of experiments in the Le Cam sense is possible (cf. Nussbaum (1996)), but only in the case \( \beta > 1/2 \), and under an additional assumption that the densities are uniformly
bounded away from 0. While asymptotic equivalence is known to fail for $\beta \leq 1/2$ (cf. Brown and Zhang (1998)), our method here yields the sup-norm constant for density estimation for all $\beta > 0$. The proof via asymptotic equivalence can be found in the technical report (Korostelev and Nussbaum (1995)).

2 Upper Asymptotic Bound

Let $g$ be a solution of the extremal problem in (3), $g \in \Sigma_0(\beta, 1)$. The correctness of this definition follows from Micchelli and Rivlin (1977), and, as shown by Leonov (1997), $g$ has a compact support. Consider also the solution $g_1 \in \Sigma_0(\beta, 1)$ of the dual extremal problem

$$
\min \{ \|g_1\|_2 \mid g_1(0) = 1, g_1 \in \Sigma_0(\beta, 1) \}.
$$

If $g$ is the solution of (3) then $g_1(u) = A_\beta^{-1} g(A_\beta^{1/\beta} u)$ (cf. section 2.2 of Donoho (1994)); hence $\|g_1\|_2 = A_\beta^{-(2\beta+1)/2\beta}$. Since $g$ is of compact support, so is $g_1$; let $S$ be a constant such that $g_1(u) = 0$ for $|u| > S$. Put $K(u) = g_1(u) / \int g_1$, $u \in \mathbb{R}^1$ and choose the bandwidth $h_n = (C\psi_n/L)^{1/\beta}$. For an arbitrary small fixed $\epsilon > 0$ define regular grid points in the interval $[0, 1]$ by

$$
x_k = \epsilon k h_n, \quad k = 0, \ldots, M,
$$

where $M = M(n, \epsilon) = (\epsilon h_n)^{-1}$ is assumed integer. Put $M_0 = \lceil S/\epsilon \rceil + 1$, and introduce the kernel estimator $f_n^*$ at the inner grid points

$$
f_n^*(x_k) = (nh_n)^{-1} \sum_{i=1}^{n} K((X_i - x_k)/h_n), \quad k = M_0, \ldots, M - M_0.
$$
Lemma 1. There exists a constant $p_0 > 0$ such that for any $\alpha > 0$ the inequality holds

$$
\sup_{f \in \Sigma(\beta, L)} P_f^{(n)}(\max_{M_0 \leq k \leq M - M_0} |f^*_n(x_k) - f(x_k)| \geq (1 + \alpha)C\psi_n) \leq p_0M^{-\alpha}.
$$

Proof. Define the bias and stochastic terms by

$$
b_{nk} = E_f[f^*_n(x_k)] - f(x_k),
$$

and

$$
z_{nk} = f^*_n(x_k) - E_f[f^*_n(x_k)].
$$

For any $\alpha > 0$ the following inequalities are true:

$$
P_f^{(n)}(\max_{M_0 \leq k \leq M - M_0} (z_{nk} + b_{nk}) \geq (1 + \alpha)C\psi_n) \leq 
$$

$$
\sum_{k=M_0}^{M - M_0} P_f^{(n)}(z_{nk} \geq (1 + \alpha)C\psi_n - \max_{M_0 \leq k \leq M - M_0} |b_{nk}|) \leq 
$$

$$
\sum_{k=M_0}^{M - M_0} P_f^{(n)}(z_{nk} \geq (1 + \alpha)C\psi_n(1 - \sup_{f \in \Sigma_0(\beta, 1), f(0) = 0} \int_{-\infty}^{\infty} K(u/h_n)f(u) \, du)) \leq 
$$

where the standard renormalization technique applies (see Donoho (1994)). Define

$$
K_\delta(u) = \delta^{-2/(2\beta + 1)}g(\delta^{-2/(2\beta + 1)}u) / \int g
$$

for any $\delta > 0$, where $g$ is again the solution of (3). The optimal recovery identity (Micchelli and Rivlin (1977), Donoho (1994)) implies that

$$
\sup_{f \in \Sigma_0(\beta, 1)} \sup_{\|z\|_2 \leq 1} \left| \int_{-\infty}^{\infty} K_\delta(u)f(u) \, du - f(0) + \delta \int_{-\infty}^{\infty} K_\delta(u)z(u) \, du \right| = \delta^{2\beta/(2\beta + 1)}A_\beta,
$$

5
hence
\[ \sup_{f \in \Sigma_0(\beta,1), f(0) = 0} \left| \int_{-\infty}^{\infty} K_\delta(u) f(u) \, du \right| + \delta \| K_\delta \|_2 = \delta^{2\beta/(2\beta+1)} A_\beta. \]

A choice \( \delta = A_\beta^{-(2\beta+1)/2\beta} \) yields
\[ K_\delta(u) = A_\beta^{1/\beta} g(A_\beta^{1/\beta} u)/ \int g = g_1(u)/ \int g_1 = K(u) \]
and hence
\[ 1 - \sup_{f \in \Sigma_0(\beta,1), f(0) = 0} \left| \int_{-\infty}^{\infty} K(u) f(u) \, du \right| = A_\beta^{-(2\beta+1)/2\beta} \| K \|_2. \]

By further calculation we obtain
\[ \sqrt{nh_n/(B_\gamma \| K \|_2^2)} C\psi_n A_\beta^{-(2\beta+1)/2\beta} \| K \|_2 = \left( \frac{2}{2\beta + 1} \log n \right)^{1/2} \]
and that for for any \( \epsilon < 1 \) and any \( n \), satisfying
\[ \log n > (2\beta + 1)(\log \epsilon^{-1} + \beta^{-1} \log (L/C)) \]
we have
\[ \left( \frac{2}{2\beta + 1} \log n \right)^{1/2} \geq \sqrt{2 \log M}. \]

Thus, the latter sum of probabilities can be estimated from above by
\[ \sum_{k=M_0}^{M-M_0} P_f^{(n)}(\sqrt{nh_n/(B_\gamma \| K \|_2^2)} z_{nk} \geq (1 + \alpha) \sqrt{2 \log M}. \]

Note that
\[ \sqrt{nh_n/(B_\gamma \| K \|_2^2)} z_{nk} = n^{-1/2} \sum_{i=1}^{n} \xi_{ik} \]
where
\[ \xi_{ik} = \sqrt{h_n/(B_\gamma \| K \|_2^2)} \left( h_n^{-1} K((X_i - x_k)/h_n) - E_f^{(n)}[h_n^{-1} K((X_i - x_k)/h_n)] \right), \]
\[ i = 1, \ldots, n, \quad k = M_0, \ldots, M - M_0. \]
The random variables $\xi_{ik}$, $i = 1, \ldots, n$, are independent for any fixed $k$, and

$$E_f^{(n)}[\xi_{ik}] = 0, \ Var_f^{(n)}[\xi_{ik}] = B_s^{-1} f(x_k) + o_n(1) \leq 1 + o_n(1) \quad (5)$$

where $o_n(1) \to 0$ as $n \to \infty$ uniformly in $i, k$, and $f \in \Sigma(\beta, L)$. Moreover, for any integer $m$, $m \geq 3$, the following bounds hold:

$$E_f^{(n)}|\xi_{ik}|^m \leq (h_n/(B_s\|K\|_2^2))^{m/2}(2B_s S 2^m H^m / h_n^{m-1}) = 2B_s S h_n (\lambda/\sqrt{h_n})^m \quad (6)$$

where $H_s = \max_{u \in \mathbb{R}^1} |K(u)|$ and $\lambda = 2H_s/\sqrt{B_s\|K\|_2^2}$. The Chebyshev exponential inequality, known as Chernoff’s upper bound, yields

$$P_f^{(n)}(\max_{M_0 \leq k \leq M-M_0} (f_n^*(x_k) - f(x_k)) \geq (1 + \alpha)C\psi_n) \leq$$

$$\sum_{k=M_0}^{M-M_0} P_f^{(n)}(n^{-1/2} \sum_{i=1}^{n} \xi_{in} \geq (1 + \alpha)\sqrt{2 \log M}) \leq M \exp (-c(1 + \alpha)\sqrt{2 \log M})(E_f^{(n)}[\exp(c\xi_{in}/\sqrt{n})])^n.$$

Using (5) and (6), we can estimate the moment generating function as follows:

$$E_f^{(n)}[\exp(c\xi_{in}/\sqrt{n})] \leq$$

$$1 + \frac{c^2}{2n} Var_f^{(n)}[\xi_{ik}] + \sum_{m \geq 3} \frac{1}{m!}(\frac{c}{\sqrt{n}})^m E_f^{(n)}|\xi_{ik}|^m \leq$$

$$1 + \frac{c^2}{2n} (1 + o_n(1)) + \frac{2B_s S \lambda^3 c}{n \sqrt{nh_n}} \sum_{m \geq 3} \frac{1}{m!}(\frac{\lambda c}{\sqrt{nh_n}})^{m-3} \leq$$

$$1 + \frac{c^2}{2n} (1 + o_n(1)) + \frac{4B_s S \lambda^3 c}{\sqrt{nh_n}} \exp(\lambda c/\sqrt{nh_n}) \leq \exp\left(\frac{c^2}{2n} (1 + o_n(1))\right). \quad (7)$$
The latter inequality is true for any $c = o_n(\sqrt{nh_n})$ as $n \to \infty$. If we choose $c = \sqrt{2 \log M}$, then (7) implies that

$$P_f^{(n)}(\max_{M_0 \leq k \leq M-M_0} (f_n^*(x_k) - f(x_k)) \geq (1 + \alpha)C\psi_n) \leq M \exp(-2(1 + \alpha) \log M) \exp((1 + o_n(1)) \log M) \leq M \exp(-(1 + \alpha) \log M) = M^{-\alpha}$$

for any $n$ large enough. The probability of the random event

$$\{\min_{M_0 \leq k \leq M-M_0} (f_n^*(x_k) - f(x_k)) \leq -(1 + \alpha)C\psi_n\}$$

admits the same upper bound, and this proves the lemma. □

To extend the definition of $f_n^*(x_k)$ to the grid points $x_k$ which are close to the endpoints of the interval $[0,1]$, we take a kernel $K_0(u)$ with the support $[0,1]$ satisfying the orthogonality conditions

$$\int_0^1 K_0 = 1, \text{ and } \int_0^1 u^j K_0 = 0, \quad j = 1, \ldots, [\beta].$$

Put

$$f_n^*(x_k) = (n\kappa h_n)^{-1} \sum_{i=1}^n K_0((X_i - x_k)/(\kappa h_n)), \quad k = 0, \ldots, M-1$$

where a small positive constant $\kappa$ is chosen in Lemma 2 below. For the grid points $x_k \in [1 - Sh_n, 1]$ we define

$$f_n^*(x_k) = (n\kappa h_n)^{-1} \sum_{i=1}^n K_0((x_k - X_i)/(\kappa h_n)), \quad k = M - M_0 + 1, \ldots, M.$$
Lemma 2. There exist constants $p_0$ and $p_1$ such that for any $n$ and for any $\alpha > 0$ the inequality holds

$$\sup_{f \in \Sigma(\beta,L)} P_f^{(n)} \left( \max_{k \in \mathcal{M}} |f_n^*(x_k) - f(x_k)| \geq (1 + \alpha) C\psi_n \right) \leq p_0 M^{-\alpha p_1}. \tag{9}$$

Proof. To prove (9), it suffices to derive the upper bound for the probability

$$P_f^{(n)} \left( \max_{0 \leq k < M_0} (f_n^*(x_k) - f(x_k)) \geq (1 + \alpha) C\psi_n \right) \leq p_0 M^{-\alpha p_1}. \tag{10}$$

The bias $b_{nk}$ of the estimator (8) at any point $x_k$ is $O((\kappa h_n)^3)$ as $n \to \infty$ (see Devroye and Györfi (1985)). Choose $\kappa$ so small that

$$|b_{nk}| \leq C\psi_n / 2, \quad k = 0, \ldots, M_0 - 1.$$

Taking into account our choice of $\kappa$, and following the lines of the proof of Lemma 1, for all $n$ large enough we have the inequalities

$$P_f^{(n)} \left( \max_{0 \leq k < M_0} (f_n^*(x_k) - f(x_k)) \geq (1 + \alpha) C\psi_n \right) \leq$$

$$\sum_{k=0}^{M_0-1} P_f^{(n)}(z_{nk} \geq (1 + \alpha) C\psi_n - C\psi_n/2) \leq$$

$$\sum_{k=0}^{M_0-1} P_f^{(n)}(\sqrt{n}\psi_n^{1/\beta} z_{nk} \geq (1/2 + \alpha) C\sqrt{\log n}) \leq$$

$$\sum_{k=0}^{M_0-1} P_f^{(n)}(n^{-1/2} \sum_{i=1}^n \xi_{ik}' \geq (1/2 + \alpha) \sqrt{\log M}).$$

where

$$\xi_{ik}' = \sqrt{\psi_n^{1/\beta}/C^2(2\beta + 1)} \left( \frac{1}{\kappa h_n} K_0 \left( \frac{X_i - x_k}{\kappa h_n} \right) - E_f^{(n)} \left[ \frac{1}{\kappa h_n} K_0 \left( \frac{X_i - x_k}{\kappa h_n} \right) \right] \right).$$

Similarly to (7) we obtain the inequality

$$E_f^{(n)}[\exp(c\xi_{in}'/\sqrt{n})] \leq \exp \left(\frac{c^2}{2n} \text{Var}_f^{(n)}[\xi_{in}'](1 + o_n(1))\right).$$
with the only difference that the variance $\text{Var}_f[\xi'_n] \leq \sigma_0^2$ is bounded by some constant $\sigma_0^2 \geq 0$ which is not necessarily 1, as in (7). Note that $M_0$ is independent of $n$. Applying Chebyshev’s exponential inequality, we have that uniformly in $f \in \Sigma(\beta, L)$

$$P_f^m(\max_{0 \leq k < M_0} (f_n(x_k) - f(x_k)) \geq (1 + \alpha) C \psi_n) \leq$$

$$M_0 \exp(-c(1/2 + \alpha) \sqrt{\log M}) \exp\left(\frac{c^2 \sigma_0^2}{2}(1 + o_n(1))\right).$$

Under the choice $c = \sqrt{\log M}/\sigma_0^2$, the latter formula yields the upper bound

$$M_0 \exp(-\frac{\alpha}{2\sigma_0^2} \log M) \leq M_0 M^{-\alpha/(2\sigma_0^2)}.$$

This completes the proof of (10), and the lemma follows. □

The derivatives $f^{(m)}(x)$, $m = 1, \ldots, [\beta]$, of a density $f \in \Sigma(\beta, L)$, can be estimated in the sup-norm with the minimax rate $O(h_\beta^{-m})$ as $n \to \infty$. We need the following version of the upper bound.

**Lemma 3.** For any $m$, $m = 1, \ldots, [\beta]$, there exists an estimator $f^{(m)}_n$ and positive constants $p_0$, $p_1$, and $C_1$ such that for any $n$ and for any $\alpha > 0$ the inequality holds

$$\sup_{f \in \Sigma(\beta, L)} P_f^m(\max_{0 \leq k < M} |f^{(m)}_n(x_k) - f^{(m)}(x_k)| \geq (1 + \alpha) C_1 h_\beta^{-m}) \leq p_0 M^{-\alpha p_1}.$$

**Proof.** Note that the upper bound in this lemma is crude since $C_1$ is not necessarily optimal. Choose the kernel $K_0(u)$ as in Lemma 2, i.e. $K_0(u)$ has support in $[0,1]$ and satisfies the orthogonality conditions. Assume that $K_0$ has $[\beta] + 1$ continuous derivatives. For a fixed $m$, $m \leq [\beta]$, put

$$f^{(m)}_n(x_k) = \frac{(-1)^m}{h_\beta^{1+m}} \sum_{i=1}^n K_0^{(m)} \left( \frac{X_i - x_k}{h_n} \right) \quad \text{if} \quad 0 \leq x_k \leq 1/2$$

and

$$f^{(m)}_n(x_k) = \frac{1}{h_\beta^{1+m}} \sum_{i=1}^n K_0^{(m)} \left( \frac{x_k - X_i}{h_n} \right) \quad \text{if} \quad 1/2 < x_k \leq 1.$$
where $K_0^{(m)}$ is the $m$th derivative of $K_0$. Standard arguments show that at each point the bias term is bounded from above by $C_2 h_n^{\beta-m}$ with a positive constant $C_2$ uniformly in $f \in \Sigma(\beta, L)$ and $x_k \in [0, 1]$. Take $C_1 > 2C_2$. Then

$$P_f^{(n)} \left( \max_{0 \leq k \leq M} |f_n^{(m)}(x_k) - f^{(m)}(x_k)| \geq (1 + \alpha)C_1 h_n^{\beta-m} \right)$$

$$\leq P_f^{(n)} \left( \max_{0 \leq k \leq M} |z_{nk}^{(m)}| \geq (1/2 + \alpha)C_1 h_n^{\beta-m} \right)$$

where $z_{nk}^{(m)} = f_n^{(m)}(x_k) - E_f^{(n)}[f_n^{(m)}(x_k)]$ are zero-mean random variables.

Following the lines of the proof of Lemma 2, we find that for all $n$ large enough the latter probability is bounded from above by

$$2M \exp(-c(1/2 + \alpha) C_1 \sqrt{\log M} \exp(\frac{\epsilon^2 \sigma_m^2}{2}))$$

with an arbitrary positive $c$ and a constant $\sigma_m^2 > 0$ independent of $n$. Choose $C_1 > \sqrt{8\sigma_m^2}$, and put $c = (1/2 + \alpha)C_1 \sqrt{\log M/\sigma_m^2}$. Direct calculations show that the latter bound turns into

$$2M \exp(-\frac{1}{2\sigma_m^2}(1/2 + \alpha)^2 C_1^2 \log M) \leq 2M^{1-4(1/2+\alpha)^2} \leq 2M^{-4\alpha}$$

which proves the lemma.

**Proof of Theorem: upper risk bound.** Take the estimators $f_n^*$ and $f_n^{(m)}$ as in Lemmas 1-3. For any $x \in [x_k, x_{k+1})$ continue $f_n^*$ as the polynomial approximation

$$f_n^*(x) = f_n^*(x_k) + \sum_{m=1}^{\lfloor \beta \rfloor} \frac{1}{m!} f_n^{(m)}(x_k) (x - x_k)^m, \quad x_k \leq x < x_{k+1}, \quad k = 0, \ldots, M - 1.$$ 

Uniformly in $f \in \Sigma(\beta, L)$ we have the inequality

$$\|f_n^* - f\|_\infty \leq L(\varepsilon h_n)^\beta / \lfloor \beta \rfloor! + \max_{0 \leq k \leq M} |f_n^*(x_k) - f(x_k)| + \sum_{m=1}^{\lfloor \beta \rfloor} \frac{1}{m!} (\varepsilon h_n)^m \max_{0 \leq k \leq M} |f_n^{(m)}(x_k) - f^{(m)}(x_k)|$$
where the first term in the right-hand side appears from the Taylor expansion of the density functions $f \in \Sigma(\beta, L)$. When the complementary events to those in Lemmas 1-3 hold, then

$$\|f_n^* - f\|_\infty \leq (1 + \alpha)(C + C_2 \varepsilon)\psi_n$$

with a positive constant $C_2$ independent of $n, \alpha$ and $\varepsilon$. Applying Lemmas 1-3, we have

$$\sup_{f \in \Sigma(\beta, L)} P_f^n(\|f_n^* - f\|_\infty \geq (1 + \alpha)(C + C_2 \varepsilon)\psi_n) \leq p_2 M^{-\alpha_0 p_3}$$

(11)

where $p_2 = (1 + [\beta])p_0$ and $p_3 = \min[1; p_1]$. Take an arbitrary small $\alpha_0$, and put

$$\alpha_j = j\alpha_0, \quad u_j = (C + C_2 \varepsilon)(1 + \alpha_j), \quad j = 1, 2, \ldots.$$  

Finally, for any continuous loss functions $w(u)$ with the polynomial majorant, we obtain from (11) that

$$\sup_{f \in \Sigma(\beta, L)} E_f^n w(\|f_n^* - f\|_\infty) \leq w((1 + \alpha_0)(C + C_2 \varepsilon)) + W_0 \sum_{j=1}^\infty (1 + u_{j+1}^2) p_2 M^{-j\alpha_0 p_3}.$$  

Since the latter sum is vanishing as $n \to \infty$, and $\alpha_0, \varepsilon$ are arbitrary small, the upper bound follows. □

3 Lower Asymptotic Bound

We first formulate a lemma in a general framework. For each $j = 1, \ldots, M$ let $Q_{j, \theta}$, $\theta \in [-1, 1]$ be a dominated family of distributions on some measurable space $(X_j, \mathcal{F}_j)$. Let $R = [-1, 1]^M$, $\theta \in R$ and let $Q_\theta = \otimes_{j=1}^M Q_{j, \theta_j}$, $\theta \in R$ be the family of product measures indexed by $\theta = (\theta_1, \ldots, \theta_M)$. Define $\|\theta\|_M = \max_{1 \leq j \leq M} |\theta_j|$.

**Lemma 4.** Let $\pi_j$ be discrete prior distributions with finite support on $[-1, 1]$, and consider the Bayes risks

$$r_{j,T}(\pi_j) = \inf_{\hat{\theta}_j} \int_{[-1,1]} Q_{j,\theta} \left( |\hat{\theta}_j - \theta| > T \right) \pi_j(d\theta), \quad j = 1, \ldots, M$$

(12)
where the infimum is taken over nonrandomized estimators \( \hat{\theta}_j \) of \( \theta \) depending only on data from \( \mathcal{X}_j \). Let \( \hat{\theta} \) denote nonrandomized estimators of \( \theta \) depending on the whole data vector \( x = (x_j)_{j=1,...,M} \), \( x_j \in \mathcal{X}_j \), let \( \pi = \otimes_{j=1}^{M} \pi_j \) and consider the Bayes risk

\[
R_T(\pi) = \inf_{\hat{\theta}} \int Q_\theta \left( \left\| \hat{\theta} - \theta \right\|_M > T \right) \pi(d\theta).
\]

Then for any \( T > 0 \)

\[
r_T(\pi) = 1 - \prod_{j=1}^{M} \left( 1 - r_{j,T}(\pi_j) \right).
\]

**Proof.** The \( j \)-th Bayes risk \( r_{j,T}(\pi_j) \) with data \( x_j \) from \( \mathcal{X}_j \) can be found as follows. Let \( Q_{j,x_j} \) be the posterior distribution for \( \vartheta \) and \( Q_j \) be the marginal distribution for \( x_j \); then

\[
\int_{[-1,1]} Q_{j,\theta} \left( \left| \hat{\vartheta}_j - \vartheta \right| > T \right) \pi_j(d\theta) = 1 - \int g_{j,T}(x_j, \hat{\vartheta}_j(x_j)) Q_j(dx_j)
\]

where \( g_{j,T} \) is the posterior gain

\[
g_{j,T}(x_j, t) = Q_{j,x_j} (|t - \vartheta| \leq T).
\]

If \( S_j \) is the finite support of \( \pi_j \) then \( Q_{j,x_j} \) is concentrated on \( S_j \subset [-1,1] \). For any \( t \in [-1,1] \) we have

\[
g_{j,T}(x_j, t) = \sum_{\vartheta \in S_j, |\vartheta - t| \leq T} Q_{j,x_j}(\{\vartheta\}).
\]

This function of \( t \) takes only finitely many values, and a maximum in \( t \) is attained on some closed interval \( t \in [t_{\min}(x_j), t_{\max}(x_j)] \). For uniqueness, take \( \hat{\vartheta}_j^*(x_j) = t_{\max}(x_j) \) as a Bayes estimator. We then have

\[
\max_{t \in [-1,1]} g_{j,T}(x_j, t) = g_{j,T}(x_j, \hat{\vartheta}_j^*(x_j)), \quad (13)
\]

\[
r_{j,T}(\pi_j) = 1 - \int g_{j,T}(x_j, \hat{\vartheta}_j^*(x_j)) Q_j(dx_j). \quad (14)
\]
Consider now the global problem: we have

\[
\begin{align*}
    r_T(\pi) &= \inf_{\hat{\theta}} \int Q_\theta \left( \left\| \hat{\theta} - \theta \right\|_M > T \right) \pi(d\theta) \\
    &= \inf_{\hat{\theta}} \int \left( 1 - \int \left( \prod_{j=1}^M \chi_{[-T,T]}(\hat{\theta}_j - \theta_j) \right) Q_\theta(dx) \right) \pi(d\theta) \\
    &= 1 - \sup_{\hat{\theta}} \int g_T(x, \hat{\theta}(x)) \prod_{j=1}^M Q_j(dx_j) \tag{15}
    \end{align*}
\]

where \( g_T(x, u) \) is the posterior gain (for \( u = (u_j)_{j=1}^M \)):

\[
    g_T(x, u) = \prod_{j=1}^M Q_j(x_j, |u_j - \theta| \leq T) = \prod_{j=1}^M g_{j,T}(x_j, u_j).
\]

Then (13) implies

\[
    \max_{u \in R} g(x, u) = \prod_{j=1}^M \max_{t \in [-1,1]} g_{j,T}(x_j, t) = \prod_{j=1}^M g_{j,T}(x_j, \hat{\theta}_j^*(x_j)).
\]

Thus a Bayes estimator of \( \theta \) is

\[
    \hat{\theta}^*(x) = (\hat{\theta}_j^*(x_j))_{j=1}^M,
\]

and from (15) and (14) we obtain

\[
\begin{align*}
    r_T(\pi) &= 1 - \int g_T(x, \hat{\theta}^*(x)) \prod_{j=1}^M Q_j(dx_j) \\
    &= 1 - \prod_{j=1}^M \int g_{j,T}(x_j, \hat{\theta}_j^*(x_j))Q_j(dx_j) \\
    &= 1 - \prod_{j=1}^M (1 - r_{j,T}(\pi_j)).
\end{align*}
\]

Back in our density problem, take a small value \( \epsilon = \epsilon(\alpha) \in (0,1) \); the final choice of \( \epsilon \) will be made below. Let \( f_\ast \in \Sigma(\beta, L) \) be such that \( f_\ast^{[\beta]}(x) \) is constant in an interval \( x \in [t_1, t_2], t_2 - t_1 \leq \epsilon \), and \( f_\ast(x) \geq B_\ast/(1 + \epsilon) \) for \( x \in [t_1, t_2] \) (cf. lemma A. 3 below).
Set \( f_0 = f_s(t_1) \); then \( f_0 \geq B_s/(1 + \epsilon) \). Consider again the solution \( g_1 \in \Sigma_0(\beta, 1) \) of the extremal problem (4); recall \( \|g_1\|_2 = A_{\beta}^{(2\beta + 1)/2\beta} \) and that \( S \) is such such that \( g_1(u) = 0 \) for \( |u| > S \). Define

\[
g_\epsilon(u) = g_1(u - S) - \epsilon g_1(\epsilon(u - 2S(1 + \epsilon^{-1}))), \quad u \in \mathbb{R}.
\]

As is easily seen, \( \int g_\epsilon = 0 \), \( \int g_\epsilon^2 = (1 + \epsilon) \|g_1\|_2^2 \) and \( g_\epsilon \in \Sigma_0(\beta, 1) \) for \( \epsilon \) sufficiently small. Set \( l_n = h_n2S(1 + 1/\epsilon) \) and redefine \( M = M(n, \epsilon) \) from section 2 as \( M = \lfloor n^{1/(2\beta + 1)(1 + \epsilon)} \rfloor \). Introduce a family of functions

\[
f(x; \theta) = f_s(x) + L_n^{\beta} \sum_{j=1}^{M} \theta_j g_\epsilon(h_n^{-1}(x - a_j)), \quad 0 \leq x \leq 1,
\]

where \( a_1 = t_1, a_{j+1} - a_j = l_n, j = 1, ..., M, \theta = (\theta_1, ..., \theta_M) \in \mathbb{R} = [-1, 1]^M \). The density \( f(x; \theta) \) differs from \( f_s(x) \) only in the interval \( [t_1, t_1 + Ml_n] \subseteq [t_1, t_2] \) for \( n \) large since \( Mh_n \to 0 \) as \( n \to \infty \) for any fixed \( \epsilon \). Since \( f_s^{[\beta]} \) is constant on \( x \in [t_1, t_2] \), we obtain that for \( \epsilon \) small enough and \( n \) sufficiently large \( f(x; \theta) \in \Sigma(\beta, L) \) for \( \theta \in \mathbb{R} \).

Put for shortness \( P_{f(x; \theta)}^{(n)} = P_{\theta}^{(n)} \) and \( E_{f(x; \theta)}^{(n)} = E_{\theta}^{(n)} \).

Define intervals \( J_j = [a_j, a_j + l_n], j = 1, ..., M \), and let \( P_{j, \theta_j} \) be the conditional distribution of \( X_1 \) given that \( X_1 \in J_j \) when \( \theta \) obtains. Let \( \kappa(\cdot, \cdot) \) be the Kullback-Leibler information number: for laws \( P_1, P_2 \) such that \( P_1 \ll P_2 \)

\[
\kappa(P_1, P_2) = \int \log \frac{dP_1}{dP_2} dP_1.
\]

Consider also

\[
\kappa_2^2(P_1, P_2) = \int \left( \log \frac{dP_1}{dP_2} \right)^2 dP_1,
\]

\[
\kappa_\infty(P_1, P_2) = \sup_{P_1} \left| \log \frac{dP_1}{dP_2} \right|.
\]
Lemma 5. Let \( \vartheta \in [0, 1] \) and consider the quantities \( \kappa = \kappa(P_1, P_2), \kappa_2 = \kappa_2(P_1, P_2) \) and \( \kappa_{\infty} = \kappa_{\infty}(P_1, P_2) \) for measures \( P_1 = P_{j, \vartheta}, P_2 = P_{j, -\vartheta} \) and \( j = 1, ..., M \). Set
\[
\mu = \frac{2(1 + \epsilon)^2}{2(\beta + 1)}, \quad n_0 = n l_n f_0.
\]
Then uniformly over \( j = 1, ..., M \), as \( n \to \infty \)

(i) \( \kappa = 2\vartheta^2 \mu_0 n_0^{-1} \log n (1 + o(1)) \) for some positive constant \( \mu_0 = \mu_0(\beta, L, \epsilon) \), \( \mu_0 \leq \mu \)

(ii) \( \kappa_2^2 = 2\kappa(1 + o(1)) \)

(iv) \( \kappa_{\infty}^2 = O(n_0^{-1} \log n) \).

Proof. Define
\[
\eta_j = l_n^{-1} \int_{J_j} f_\ast(x)dx.
\]
The distribution \( P_{j, \vartheta} \) has density
\[
f_j(x; \vartheta) = (f_\ast(x) + \vartheta L h_n \beta g_\epsilon(h_n^{-1} (x - a_j))/l_n \eta_j, \ x \in J_j.
\]
Observe that \( f_\ast(x) = f_0 + o(1) \) and \( \eta_j = f_0 + o(1) \) uniformly in \( j \) and \( x \). In the sequel we use notation \( o^\ast(1), O^\ast(1) \) for quantities which are \( o(1) \) or \( O(1) \) as \( n \to \infty \) uniformly over \( x \in J_j \) and \( j = 1, ..., M \). Recall \( f_0 \geq B_\ast/(1 + \epsilon) \). Define further
\[
z_j(x) = L h_n \beta g_\epsilon(h_n^{-1} (x - a_j))/f_\ast(x);
\]
we then obtain
\[
f_j(x; \vartheta) = l_n^{-1}(1 + \vartheta z_j(x))(1 + o^\ast(1)), \ x \in J_j.
\]
Now \( \int g_\epsilon = 0 \) entails
\[
\int z_j(x)f_\ast(x)dx = 0
\]
and as a consequence
\[
\int z_j(x)f_j(x; \vartheta)dx = \vartheta l_n^{-1}\left(\int z_j^2(x)dx\right)(1 + o^\ast(1)).
\]
Note the following relation: for $0 < z \to 0$

$$\log \frac{1 + z}{1 - z} = 2z + O(z^3). \quad (20)$$

Note also

$$z_j^2(x) = O^*(h_n^{2\beta}) \quad (21)$$

and the following equalities of order of magnitude (denoted $\asymp$), which are immediate consequences of our definitions:

$$h_n^{2\beta} \asymp (\log n/n)^{2\beta/(2\beta+1)} \asymp n_0^{-1} \log n. \quad (22)$$

**Proof of (i).** We have

$$\kappa = \int \log \frac{1 + \vartheta z_j(x)}{1 - \vartheta z_j(x)} f_j(x; \vartheta) dx;$$

consequently, in view of (19) and (20)

$$\kappa = 2\vartheta \int z_j(x) f_j(x; \vartheta) dx + O(|z_j(x)|^3)$$

$$= 2\vartheta l_n^{-1} \left( \int z_j^2(x) dx \right) (1 + o^*(1)) + O^*(n_0^{-1} \log n)^{3/2}. \quad (23)$$

Note that

$$l_n^{-1} \int z_j^2(x) dx = l_n^{-1} f_0^{-2} L^2 h_n^{(2\beta+1)} (1 + \varepsilon) \|g_1\|^2 (1 + o^*(1)).$$

Recall $\|g_1\|^2 = A_\beta^{-2(2\beta+1)/\beta}$; an evaluation of the r. h. s. above yields

$$l_n^{-1} \int z_j^2(x) dx = (B_*/f_0(1 + \varepsilon)) \mu n_0^{-1} \log n(1 + o^*(1)). \quad (24)$$

Set $\mu_0 = (B_*/f_0(1 + \varepsilon))\mu$; then $\mu_0$ depends on $\varepsilon$, $\beta$, $B_*$, $B_*(\beta, L)$ and $f_0 = f_*(t_1)$, and the function $f_*$ can be selected to depend only on $\beta$ and $L$ (cf. Lemma A.3). The inequality $f_0 \geq B_*/(1 + \varepsilon)$ now completes the proof of (i).
Proof of (ii). We have
\[
\kappa = \int \left( \log \frac{1 + \vartheta z_j(x)}{1 - \vartheta z_j(x)} \right)^2 f_j(x; \vartheta) dx
\]
\[
= \int \left( 2\vartheta z_j(x) + O^*((n_0^{-1} \log n)^{3/2}) \right)^2 f_j(x; \vartheta) dx
\]
\[
= 4\vartheta^2 \left( \int z_j^2(x) f_j(x; \vartheta) dx \right) + O^*((n_0^{-1} \log n)^2)
\]
\[
= 4\vartheta^2 l_n^{-1} \left( \int z_j^2(x) dx \right) (1 + o^*(1)) + O^*((n_0^{-1} \log n)^{3/2})
\]
so that (ii) follows from (23) and (24).

Proof of (iii). This is an immediate consequence of (18), (21) and (22). □

Let us state a result on large deviations for sums of i. i. d. random variables. Let $Z, Z_1, Z_2, \ldots$ be a sequence of independent real random variables with common law $Q$.

Lemma 6. Assume

(i) $E_Q Z = 0$, $\text{Var}_Q Z = 1$

(ii) there exists a positive constant $C$ such that $|Z| \leq C$ $Q-$a.s.

Let $x_n$ be a sequence such that $x_n \to \infty$, $x_n = o(n^{1/2})$. Then for every $\delta > 0$ we have

\[
\Pr_Q \left( n^{-1/2} \sum_{i=1}^n Z_i > x_n \right) \geq \exp \left( -x_n^2 (1 + \delta)/2 \right) (1 + o(1)), \ n \to \infty
\]

uniformly over all $Q$ fulfilling (i) and (ii) for a given constant $C$.

Proof. For the moment generating function of $Z$ we have an expansion

\[
E \exp(tZ) = 1 + t^2/2 + \phi
\]

with a remainder term satisfying

\[|\phi| \leq |t|^3 C^3 e^C/3!\]

uniformly over the class of distributions fulfilling (i) and (ii). Hence uniformly over $Q$ the following lower bound holds:
\[
\lim_{n \to \infty} (x_n^{-2}) \log \Pr_Q((Z_1 + \ldots + Z_n)/(x_n \sqrt{n}) > 1) \geq (-1/2)
\]

(see Wentzell (1990), Theorem 4.4.1, or Freidlin and Wentzell (1984), Section 5.1, Example 4.) Thus, for all \( n \) large uniformly over \( Q \) satisfying (i), (ii) we have

\[
\log \Pr_Q((Z_1 + \ldots + Z_n)/\sqrt{n} > x_n) \geq (-1/2 - \delta)x_n^2
\]

and the lemma follows. \( \square \)

For measures \( P_1, P_2 \) and \( P_0 = P_1 + P_2 \) let \( \Pi(P_1, P_2) \) be the testing affinity between \( P_1 \) and \( P_2 \)

\[
\Pi(P_1, P_2) = \int \min(dP_1/dP_0, dP_2/dP_0) dP_0.
\]

Let \( \nu \) be natural and consider the \( \nu \)-fold product measure \( P_j^{\otimes \nu} \) of \( P_{j, \vartheta} \) with itself, for fixed \( \vartheta \in [0, 1] \) and for \(-\vartheta\), and \( j = 1, \ldots, M \).

**Lemma 7.** Let \( \vartheta \in [0, 1] \) assume that

\[
n_0(1 - \epsilon) \leq \nu \leq n_0(1 + \epsilon).
\]

Then if \( \epsilon \) is sufficiently small,

\[
\Pi(P_j^{\otimes \nu}, P_{j, -\vartheta}^{\otimes \nu}) \geq 2n^{-\vartheta^2 \mu'}(1 + o(1))
\]

uniformly over \( j = 1, \ldots, M \), where

\[
\mu' = (1 + \epsilon)^6/(2\beta + 1).
\]

**Proof.** It is well known that if \( P_1 \ll P_2 \) and \( P_2 \ll P_1 \) then

\[
\Pi(P_1, P_2) = P_1(dP_2/dP_1 \geq 1) + P_2(dP_1/dP_2 > 1).
\]
Set \( P_1 = P_{j, \vartheta}^{\otimes \nu} \), \( P_2 = P_{j, -\vartheta}^{\otimes \nu} \) and consider i. i. d. random variables \( \lambda_1, \ldots, \lambda_{\nu} \), having the law of

\[
\lambda = \log \left( \frac{dP_{j, -\vartheta}}{dP_{j, \vartheta}} \right)
\]

under \( P_{j, \vartheta} \). Then

\[
P_1 \left( \frac{dP_2}{dP_1} \geq 1 \right) = P_{j, \vartheta}^{\otimes \nu} \left( \sum_{i=1}^{\nu} \lambda_i \geq 0 \right).
\]

(25)

Note that

\[
E\lambda = -\kappa(P_{j, \vartheta}, P_{j, -\vartheta}),
\]

\[
\text{Var}\lambda = \kappa^2(P_{j, \vartheta}, P_{j, -\vartheta}) - \kappa^2(P_{j, \vartheta}, P_{j, -\vartheta})
\]

\[
= 2\kappa(P_{j, \vartheta}, P_{j, -\vartheta})(1 + o^*(1))
\]

according to lemma 5. Set \( \lambda_i^* = (\lambda_i - E\lambda)/(\text{Var}\lambda)^{1/2} \), \( i = 1, \ldots, \nu \); then (25) takes the form

\[
P_1 \left( \frac{dP_2}{dP_1} \geq 1 \right) = P_{j, \vartheta}^{\otimes \nu} \left( \nu^{-1/2} \sum_{i=1}^{\nu} \lambda_i^* \geq -\nu^{1/2} E\lambda/(\text{Var}\lambda)^{1/2} \right).
\]

We use lemma 6 for a lower bound to this large deviation probability. Note that

\[
\text{Var}\lambda_i^* = 1, \text{ and}
\]

\[
|\lambda_i^*| = |\lambda_i - E\lambda|/(\text{Var}\lambda)^{1/2} \leq (\kappa^2(P_{j, \vartheta}, P_{j, -\vartheta}))^{-1/2} 2\kappa \kappa^2(P_{j, \vartheta}, P_{j, -\vartheta})^{-1/2}
\]

which according to lemma 5 is uniformly bounded for all sufficiently large \( n \). This lemma also yields

\[
-\nu^{1/2} E\lambda/(\text{Var}\lambda)^{1/2} \leq (1 + \epsilon)^{1/2} n_0^{1/2} 2^{-1/2} (\kappa(P_{j, \vartheta}, P_{j, -\vartheta}))^{1/2}(1 + o^*(1))
\]

\[
\leq (1 + \epsilon) \mu^{1/2} (\log n)^{1/2}
\]

(26)

for sufficiently large \( n \). Moreover since (cp. (22))

\[
\nu \asymp n_0 \asymp n^{23/(2\beta + 1)}(\log n)^{1/(2\beta + 1)}
\]

20
it follows that the r. h. s. of (26) is of order \((\log \nu)^{1/2}\), hence \(o(\nu^{1/2})\). Thus lemma 6 is applicable for \(x_n = (1 + \epsilon)\partial \mu^{1/2}(\log n)^{1/2}\): for every \(\delta > 0\)

\[
P_1 \left( \frac{dP_2}{dP_1} \geq 1 \right) \geq \exp \left( \frac{1}{2} x_n^2 (1 + \delta) \right) (1 + o^*(1)).
\]

Selecting \(\delta = \epsilon\), we obtain we obtain

\[
P_1 \left( \frac{dP_2}{dP_1} \geq 1 \right) \geq n^{-\partial^2 (1+\epsilon)^2 \mu/2} (1 + o^*(1))
\]

For \(P_2 (dP_1/dP_2 \geq 1)\) this lower bound is proved analogously. \(\square\)

Define numbers

\[
\nu_j = \sum_{i=1}^{n} \chi_{J_j}(X_i), \quad j = 1, \ldots, M.
\]

(27)

The joint distribution of \(\nu = (\nu_1, \ldots, \nu_M)\) under \(P_\theta^{(n)}\) does not depend \(\theta\); call it \(P^{(n)}\nu\).

**Lemma 8.** For the event

\[
\mathcal{N}_n = \left\{ \sup_{j=1, \ldots, M} |\nu_j/n_0 - 1| < \epsilon \right\}
\]

where \(n_0\) is given by (17), we have

\[
P^{(n)}\nu(\mathcal{N}_n) \to 1.
\]

**Proof.** Note that \(\nu_j\) is a sum of i. i. d. Bernoulli random variables \(\chi_{J_j}(X_i), i = 1, \ldots, n\) with expectation \(\int_{J_j} f_*\) and variance \((\int_{J_j} f_*)(1 - \int_{J_j} f_*)\). Let \(n_j = n \int_{J_j} f_*\). Bennett’s inequality (Shorack, Wellner (1986), Appendix A, p. 851) yields for any \(\epsilon' > 0\)

\[
P^{(n)}\nu(\nu_j - n_j \geq n_j \epsilon') \leq \exp(-\epsilon' n_j^{1/2} C_{\epsilon'})
\]

for a constant \(C_{\epsilon'}\). Observe \(\frac{1}{n} \int_{J_j} f_* = f_0 + o(1)\) uniformly in \(j\), hence \(n_j/n_0 \to 1\) uniformly. Note also

\[
|\nu_j/n_0 - 1| \leq |\nu_j/n_j - 1| (n_j/n_0) + |n_j/n_0 - 1|.
\]

21
Select $\epsilon' \leq \epsilon/3$ and $n$ sufficiently large such that $|n_j/n_0 - 1| < \epsilon'$; then (28) and $M = [n^{1/((2\beta+1)(1+\epsilon))}]$ imply the assertion. □

**Proof of Theorem: lower risk bound.** We omit those details which are similar to the Gaussian case in Korostelev (1993). It suffices to prove that for an arbitrary estimator $\hat{f}_n$ and for any small $\alpha > 0$

$$\liminf_{n \to \infty} \sup_{f \in \Sigma(\beta,L,b)} P_f^{(n)} \left( \|\hat{f}_n - f\|_\infty > (1 - \alpha)C\psi_n \right) = 1.$$  

Standard arguments show that this is implied by

$$\liminf_{n \to \infty} \sup_{\theta \in R} P_\theta^{(n)} \left( \|\hat{\theta}_n - \theta\|_M > 1 - \alpha \right) = 1 \tag{29}$$

where $\hat{\theta}_n = (\hat{\theta}_{n1}, ..., \hat{\theta}_{nM})$ is an arbitrary estimator of $\theta = (\theta_1, ..., \theta_M)$, $\|\theta\|_M = \max_{1 \leq j \leq M} |\theta_j|$. For the intervals $J_j = [a_j, a_j + l_n]$ define conditional empirical distribution functions

$$\bar{F}_{nj}(t) = \nu_j^{-1} \sum_{i=1}^{n} \chi_{[a_j, a_j + l_n]}(X_i), t \in [0,1], \quad j = 1, ..., M,$$

where $\nu_j$ are defined in (27).

Though the random variables $\bar{F}_{nj}$ under $P_\theta^{(n)}$ are dependent via the sample $X_1, ..., X_n$, they are conditionally independent given the number of sample points in each $J_j$. Thus for sets $D_1, \ldots, D_M$ in the appropriate sample space

$$P_\theta^{(n)} \left( \bar{F}_{n1} \in D_1, ..., \bar{F}_{nM} \in D_M \mid \nu_1 = n_1, ..., \nu_M = n_M \right) = \prod_{j=1}^{M} P_\theta^{(n)} \left( \bar{F}_{nj} \in D_j \mid \nu_j = n_j \right). \tag{30}$$

Let $P_{\nu_j}^{(n)}$ be the conditional distribution of the process $\bar{F}_{nj}$ given $\nu_j$; define also a conditional empirical for the complement of $\cup_{j=1}^{M} J_j$ in $[0,1]$ and let $P_0^{(n)}$ its conditional distribution given $\nu = (\nu_1, ..., \nu_M)$. Then $P_{\theta,\nu}^{(n)} = \left( \bigotimes_{j=1}^{M} P_{\theta_{j},\nu_j}^{(n)} \right) \otimes P_0^{(n)}$ represents
the conditional distribution of the whole sample \(X_1, \ldots, X_n\) given \(\nu\). Recall that \(P^{(n)\nu}_{\theta}\) is the joint \(P^{(n)}_{\theta}\)-distribution of \(\nu\), which is independent of \(\theta \in R\). Put \(C_n = \{||\hat{\theta}_n - \theta||_M > 1 - \alpha\}\). Consider a prior distribution \(\pi = \otimes_{j=1}^M \pi_j\) on \(R\) where each \(\pi_j\) has finite support in \([-1, 1]\). Then

\[
\inf_{\hat{\theta}_n} \sup_{\theta \in \mathcal{R}} P^{(n)}_{\theta, \nu}(C_n) \geq \inf_{\hat{\theta}_n} \int_{\mathcal{R}} \int_{\mathcal{N}_n} P^{(n)}_{\theta, \nu}(C_n) P^{(n)\nu}(d\nu) \pi(d\theta)
\]

\[
\geq P^{(n)\nu}(\mathcal{N}_n) \inf_{\nu \in \mathcal{N}_n} \inf_{\hat{\theta}_n} \int_{\mathcal{R}} P^{(n)}_{\theta, \nu}(C_n) \pi(d\theta).
\]

In view of lemma 8 it now suffices to prove

\[
\inf_{\nu \in \mathcal{N}_n} \inf_{\hat{\theta}_n} \int_{\mathcal{R}} P^{(n)}_{\theta, \nu}(C_n) \pi(d\theta) \geq 1 + o(1). \quad (31)
\]

Applying Lemma 4 we obtain

\[
\inf_{\hat{\theta}_n} \int_{\mathcal{R}} P^{(n)}_{\theta, \nu}(C_n) \pi(d\theta) \geq 1 - \prod_{j=1}^M (1 - r_{j,1-\alpha}(\pi_j)) \quad (32)
\]

where \(r_{j,1-\alpha}(\pi_j)\) is the Bayes risk (12) for \(Q_{j,\theta_j} = P^{(n)}_{j,\theta_j,\nu_j}, T = 1 - \alpha\). Now let us estimate this Bayes risk in each of the \(M\) (conditionally) independent problems, for \(\nu \in \mathcal{N}_n\).

Note that each measure \(P^{(n)}_{j,\theta_j,\nu_j}\) can be construed as coming from an i. i. d. sample of size \(\nu_j\) governed by the conditional distribution of \(X_1\) given \(J_j\); i. e. by \(P_{j,\theta_j}\). Consider a test of the hypothesis \(\theta_j = \theta_j^+ = 1 - \alpha/2\) vs. \(\theta_j = \theta_j^- = -(1 - \alpha/2)\). Let \(\pi_j\) be uniform on \(\{\theta_j^+, \theta_j^+\}\); then we have (cf. e. g. Strasser (1985), 14. 5. (4))

\[
r_{j,1-\alpha}(\pi_j) \geq \frac{1}{2} \Pi(P^{(n)}_{j,\theta_j^+,\nu_j}, P^{(n)}_{j,\theta_j^-,\nu_j}).
\]

Now apply lemma 7, noting that

\[
\Pi(P^{(n)}_{j,\theta_j^+,\nu_j}, P^{(n)}_{j,\theta_j^+,\nu_j}) = \Pi(P^{\otimes\nu_j}_{j,\theta_j^+,\nu_j}, P^{\otimes\nu_j}_{j,\theta_j^+,\nu_j})
\]

and that on \(\mathcal{N}_n\) we have \(n_0(1 - \epsilon) \leq \nu_j \leq n_0(1 + \epsilon)\). We get

\[
r_{j,1-\alpha}(\pi_j) \geq n^{-(1-\alpha/2)^2 \nu} \quad (33)
\]

23
for all \( j = 1, \ldots, M \) if \( n \) is large enough. Hence for the r. h. s. in (32) we obtain a lower bound
\[
\geq 1 - \prod_{j=1}^{M} \left( 1 - n^{-\left(1-\alpha/2\right)^2\mu'} \right) \geq 1 - \exp \left( -Mn^{-\left(1-\alpha/2\right)^2\mu'} \right).
\]
(34)

We get \( Mn^{-\left(1-\alpha/2\right)^2\mu'} = (1 + o(1))n^{\mu''} \) for an exponent
\[
\mu'' = \frac{1}{(2\beta + 1)(1 + \epsilon)} - (1 - \alpha/2)^2\mu'
\]
\[= \frac{1}{(2\beta + 1)(1 + \epsilon)} - (1 - \alpha/2)^2(1 + \epsilon)^6/(2\beta + 1).\]

For given \( \alpha > 0, \epsilon \) can be chosen such that \( \mu'' > 0 \). In that case \( \exp \left( -Mn^{-\left(1-\alpha/2\right)^2\mu'} \right) \to 0 \) and (34) implies (31).

\( \square \)

4 Appendix: Analytic Facts

The fact that densities of the class \( \Sigma(\beta, L) \) are uniformly bounded in sup-norm follows from standard imbedding theorems.

**Lemma A 1.** For any \( L > 0 \) and \( \beta > 0 \)
\[
B_s(\beta, L) = \max_{f \in \Sigma(\beta, L)} \max_{0 \leq x \leq 1} f(x) < +\infty.
\]

**Proof.** Apply Theorem 17.4 of Besov, Il’in and Nikol’skii (1979), using the fact that \( f \) is bounded in \( L_1 \)-norm on \([0, 1] \).

For \( \beta \leq 1 \) the value of \( B_s(\beta, L) \) can be found.

**Lemma A 2.** For any \( L > 0 \) and \( 0 < \beta \leq 1 \)
\[
B_s(\beta, L) = \frac{((\beta + 1)/\beta)^{(\beta+1)}}{\beta + 1} \] if \( L \geq (\beta + 1)/\beta, \)
\[
= 1 + L/(\beta + 1) \] if \( L \leq (\beta + 1)/\beta. \]

24
Proof. It can be shown that the extremal density is

\[ f(x) = \max(\{f(0) - Lx^\beta, 0\}, x \in [0, 1]). \]

An easy calculation from \( \int f(x)dx = 1 \) yields \( f(0). \) □

Lemma A 3. For any \( L > 0 \) and \( \beta > 0, \) and every \( \epsilon \in (0, 1) \) there are \( t_1, t_2 \in [0, 1], \)

\( 0 < t_2 - t_1 \leq \epsilon \) and a function \( f_* \in \Sigma(\beta, L) \) such that for all \( x \in [t_1, t_2], \)

\[ f_*(x) \geq B_*(\beta, L)/(1 + \epsilon), \quad (35) \]

\[ f_*^{[\beta]}(x) = f_*^{[\beta]}(t_1). \]

Proof. Let \( f \) be a solution in \( f \) of the problem (2), i.e. \( \|f\|_\infty = B_*(\beta, L). \) Let \( \bar{\epsilon} \in (0, \epsilon) \)

and let \( t_1, t_2 \in [0, 1], \) \( t_2 - t_1 = \bar{\epsilon} \) be such that \( f(x) \geq B_*(\beta, L)/(1 + \epsilon/2) \) for \( x \in [t_1, t_2]. \)

Since \( f \in \Sigma(\beta, L) \) is continuous on \([0, 1], \) such \( t_1, t_2 \in [0, 1] \) exist for sufficiently small \( \bar{\epsilon}. \) Let \( m = [\beta], \gamma = \beta - m \) and let \( t_0 \in [t_1, t_2] \) be such that \( f^{(m)}(t_0) \geq f^{(m)}(x), \) for \( x \in [t_1, t_2]. \) Since \( f^{(m)} \) is continuous, such a \( t_0 \) exists. Define a function \( g_0 \) by

\[ g_0(x) = f^{(m)}(t_0) - f^{(m)}(x), \quad x \in [t_1, t_2] \]

\[ = f^{(m)}(t_0) - f^{(m)}(t_2), \quad x \in (t_2, 1] \]

\[ = f^{(m)}(t_0) - f^{(m)}(t_1), \quad x \in [0, t_1). \]

Note that \( g_0(x) \geq 0, x \in [0, 1] \) and

\[ \|g_0\|_\infty \leq L |t_2 - t_1|^{\gamma} = L \bar{\epsilon}^{\gamma}. \]

Let \( Q \) be the integral operator \( Qg(t) = \int_0^t g(u)du, \) \( t \in [0, 1] \) and define \( \hat{g} = Q^mg_0 \)

\((m\text{-fold application of } Q). \) Then \( \hat{g}(x) \geq 0, x \in [0, 1] \) and

\[ \|\hat{g}\|_\infty \leq \|g_0\|_\infty \leq L \bar{\epsilon}^{\gamma}. \] (36)
Define $\tilde{f} = f + \tilde{g}$. Since $\tilde{f}^{(m)}(t) = f^{(m)}(t_0)$ on $[t_1, t_2]$ while $\tilde{f}^{(m)}(t) - f^{(m)}(t)$ is constant outside $(t_1, t_2)$, it follows that

$$|\tilde{f}^{(m)}(x_1) - \tilde{f}^{(m)}(x_2)| \leq L |x_1 - x_2|^{\gamma}, \quad x_1, x_2 \in [0, 1].$$

Furthermore, $\tilde{f} \geq f$ and by (36)

$$\left\| \tilde{f} - f \right\|_\infty \leq L \tilde{\epsilon}^\gamma.$$

Defining $f_* = \tilde{f} / \int \tilde{f}$, we see that $f_*$ is a density in $\Sigma(\beta, L)$. Moreover, $f_*(x) \geq B_*(\beta, L)/(1 + \epsilon/2) \int \tilde{f}$ for $x \in [t_1, t_2]$. By selecting $\tilde{\epsilon}$ sufficiently small, we achieve (35).
